

Options

In this package there are four categories of options (examples and differences will be shown further)

1. for interval notation
 - `isointerval` for using standardized format of interval described in **ISO 31-11**
 - `isoointerval` for using standardized alternative format of interval described in **ISO 31-11**
 - `fnspeinterval` for using special notation used at FNSPE CTU in Prague
2. for tensor notation (now for vectors and matrices)
 - `isotensor` for using standardized format of tensor
 - `undertensor` for using underline notation of tensor
 - `arrowtensor` for using arrow notation of tensor
3. for complex notation (real and complex part)
 - `isocomplex` for using standardized format of complex and real part
 - `oldcomplex` for using old L^AT_EX default format of complex and real part
4. for definition notation
 - `deftext` for definition using *def.* over the equal
 - `defcolon` for definition using the colon with equal

Macros

Interval

Let a and b be real numbers.

Closed interval

Using of macro

```
\ci{a}{b}
```

as closed interval.

- `isointerval` $[a, b]$

- `isointerval` (same as for `isointerval`)

$[a, b]$

- `fnspeinterval`

$\langle a, b \rangle$

Opened interval

Using of macro

`\oi{a}{b}`

as opened interval.

- `isointerval`

$]a, b[$

- `isointerval`

(a, b)

- `fnspeinterval` (same as for `isointerval`)

(a, b)

Right closed interval

Using of macro

`\rci{a}{b}`

as right closed interval.

- `isointerval`

$]a, b]$

- `isointerval`

$(a, b]$

- `fnspeinterval`

(a, b)

Left closed interval

Using of macro

`\lci{a}{b}`

as left closed interval.

- `isointerval`

$[a, b[$

- `isointerval` (same as for `isointerval`)

$[a, b)$

- `fnspeinterval`

$\langle a, b \rangle$

Using in text

All these macros can be used directly in text (thanks to the command *ensure-math*). Therefore one can use this syntax

```
Let  $x$  be in  $[a, b]$ 
```

which casts: Let x be in $[a, b]$.

Tensor

Let x be vector and A be matrix.

Vector

Using of macro

```
 $\vec{x}$ 
```

as **vector**.

- isotensor - small letter with italic boldface

\mathbf{x}

- undertensor

\underline{x}

- arrowtensor

\vec{x}

Matrix

Using of macro

```
 $\mathbf{A}$ 
```

as **matrix**.

- isotensor - capital letter with italic boldface

\mathbf{A}

- undertensor

\underline{A}

- arrowtensor

$\leftrightarrow A$

Using in text

All these macros can be used directly in text (thanks to the command *ensure-math*). Therefore one can use this syntax

```
Let \vec{x} be real.
```

which casts: Let \vec{x} be real.

Macro for set

Set of natural numbers from 1 to n

Using of macro

```
\allset{n}
```

as **all** natural number up to n **set** leads to

$$\{1, 2, \dots, n\}.$$

Set of natural numbers from 0 to n

Using of macro

```
\allsetzero{n}
```

as **all** natural number up to n **set** with **zero** leads to

$$\{0, 1, \dots, n\}.$$

Differentiability class

Just symbol

Using of macro

```
\cclass
```

as **C class** leads to

$$\mathcal{C}.$$

C infinity

Using of macro

```
\ccinf
```

as **C class** of **infinity** leads to

$$\mathcal{C}^\infty.$$

C of order d

Using of macro

```
\ccof{d}
```

as **C class** of order leads to

$$\mathcal{C}^d.$$

Complex

Let $z \in \mathbb{C}$.

Real part

Using of macro

`\Re{x}`

as **Real**.

- `oldcomplex`

$\Re\{z\}$

- `isocomplex`

$\operatorname{Re} z$

Imaginary part

Using of macro

`\Im{x}`

as **Imaginary**.

- `oldcomplex`

$\Im\{z\}$

- `isocomplex`

$\operatorname{Im} z$

Using in text

All these macros can be used directly in text (thanks to the command *ensure-math*). Therefore one can use this syntax

`Let x equal to $\Re\{z\}$.`

which casts: Let x equal to $\operatorname{Re} z$.

Subscript

Subscript text with two or more characters should be written in roman style (not italic as default). One can use prefix `!` which makes the word after it in roman style. Using of macro

`A_{!unique}`

which leads to

A_{unique}

instead of classic

$A_{\textit{unique}}$

Floor and ceiling functions

Floor function

Macro

```
\floor{x}
```

as **floor** function leads to

$$\lfloor x \rfloor$$

Ceil function

Macro

```
\ceil{x}
```

as **ceil** function leads to

$$\lceil x \rceil$$

Definition operator

There are two ways to set a definition operator. First with *text* and the second with *colon*.

Text definition

Macro

```
x \df a
```

- `deftext`

$$x \stackrel{\text{def.}}{=} a$$

- `defcolon`

$$x := a$$

Special sets of numbers

Natural number

Macro

```
\natun
```

as **natural number** leads to

$$\mathbb{N}$$

Natural number with zero included

Macro

```
\nnzero
```

as **natural number zero** leads to

$$\mathbb{N}_0$$

Integers

Macro

`\inte`

as **interegers** leads to

\mathbb{Z}

Rational number

Macro

`\ratin`

as **rational number** leads to

\mathbb{Q}

Real number

Macro

`\realn`

as **real number** leads to

\mathbb{R}

Complex number

Macro

`\compn`

as **complex number** leads to

\mathbb{C}

Using in text

All these macros can be used directly in text (thanks to the command *ensure-math*). Therefore one can use this syntax

`Let n be in \natun`

which casts: Let n be in \mathbb{N} .

Derivative

It is derived from *physics* package. The manual is here.

Operator

Partially derived from *physics* package.

Gradient

Macro

`\grad`

as **gradient** leads to

∇

Divergence

Macro

`\div`

as **divergence** leads to

$\nabla\cdot$

Derived from *physics* package, the original meaning of this command as a maths symbol for dividing has alias

`\divisionsymbol`

which cast

\div

Rotation

In English literature as **curl** operator has macro

`\rot`

as **rotation** and leads to

$\nabla\times$

One can also use *physics* package command

`\curl`

Laplacian

Macro

`\lapl`

as **laplacian** leads to

Δ

One can also use *physics* package notation

∇^2

which is cast by macro

`\laplacian`

Degree

Macro

```
\degree
```

as **degree** leads to $^\circ$. Can be used without math mode.

Physics unit

Variable unit

Macro

```
\varun{m}{kg}
```

as **variable unit** leads to

$$[m] = \text{kg}$$

This macro can be used directly in text (thanks to the *ensure* function). Therefore one can use

```
where \varun{m}{kg} is the mass.
```

which casts: where $[m] = \text{kg}$ is the mass.

Unit

Macro

```
m\unit{kg}
```

as **unit** leads to

$$m \text{ kg}$$

This macro looks as

```
\;\mathrm{kg}
```

the space before the roman characters is very important in science publications.

Expected value

Macro

```
\expv{x}
```

as **expected value** leads to

$$\langle x \rangle$$

Shortcuts

One half

Macro

```
\half
```

as **half** leads to

$$\frac{1}{2}$$

One over

Macro

```
\oover{x}
```

as **one over** leads to

$$\frac{1}{x}$$

Spaces

Horizontal space

Macro

```
\hem[width]
```

as `hspace{em}` leads to horizontal space of specific width (multiples of em).
Special case is 1em

```
\mathrm{text}\hem\mathrm{text}
```

which leads to

text text

or shortcut form space with 2em width

```
\mathrm{text}\h2em\mathrm{text}
```

which casts

text text

Implies with em spaces

Macro

```
\impem
```

as **implies** with **em** spaces leads to

text \Rightarrow text
